

Technical SEO Audit — retailzpos.com

Prepared for: RetailzPOS (marketing@ptechpos.com) **Date:** July 21, 2026 **Auditor:** SEO Specialist (technical audit persona) **Scope:** www.retailzpos.com — crawlability, indexability, on-page/meta, structured data, site architecture, performance signals, mobile/technical, and content-gap analysis for the liquor store / convenience store / smoke shop ICP.

Methodology note — read before the findings

This audit was supposed to be built on direct HTTP inspection (`curl` for headers/robots.txt/sitemap.xml/raw `<head>` , plus rendered fetches of key pages). **That direct access was not available in this environment:** both the sandbox's outbound `curl` /Bash networking and the WebFetch tool returned `403 Forbidden` for **every** external host tested — not just retailzpos.com. I confirmed this is an environment-level egress restriction, not a retailzpos.com-specific block, by testing the identical request against `example.com` and `www.google.com` , which also failed with the same `403 / CONNECT tunnel failed` signature (egress proxy `x-deny-reason: host_not_allowed`). Per the operating instructions for this sandbox, that class of failure is a policy denial to be reported, not worked around.

To avoid fabricating an audit, I did **not** invent header values, exact meta description text, canonical tags, JSON-LD payloads, alt attributes, or performance metrics. Instead I used **Google's live search index** (via `site:` operators and targeted queries) as an indirect but real, verifiable window into what Google currently sees on the site — indexed URLs, indexed page titles, and index coverage/duplication patterns. Everything below sourced this way is flagged as **[Index-derived]**. Everything I could not verify at all is listed explicitly in the "Could Not Verify" section — treat that list as the top of your own team's to-do list using tools that have real network access to the site (Screaming Frog, GSC, PageSpeed Insights, or simply `curl` from a normal machine).

1. Executive Summary

RetailzPOS's organic footprint shows a site that is actively indexed by Google, has genuine industry-vertical content (liquor, smoke shop, convenience store), and reasonable third-party trust signals (Birdeye 4.5★/30 reviews, Capterra, GetApp, Software Advice, G2 listings). However, the index reveals concrete technical debt: a **duplicated, non-descriptive title tag reused across at least four unrelated pages**, a **legacy /home-old/ duplicate homepage still indexed**, a **second live, separately-indexed domain (retailzpos.com non-www, serving a Canada section)** alongside `www.retailzpos.com` with no visible canonicalization, and **keyword cannibalization** across three-plus pages competing for "liquor store POS system." None of these are catastrophic, but together they're diluting ranking signal and are the kind of low-effort/high-impact fixes an SEO audit exists to catch. Because this session could not make direct HTTP requests to the live site, true crawl-level checks (headers, robots.txt, sitemap.xml, canonical tags, structured data, alt text, Core Web Vitals) still need to

be run by someone with normal network access — that is the single biggest gap in this report and should be the immediate follow-up.

2. Findings by Category

A. Crawlability & Indexability

Issue	Where	Why it matters	Recommended fix
Could not verify robots.txt contents	<code>https://www.retailzpos.com/robots.txt</code>	Can't confirm nothing important (e.g. <code>/blog/</code> , <code>/liquor-store-pos-system/</code>) is disallowed, or that a sitemap directive is present.	Team should open the URL directly and confirm: (1) no disallow rules block money pages, (2) a <code>Sitemap:</code> line points to a valid, current sitemap.
Could not verify sitemap.xml / sitemap index	<code>https://www.retailzpos.com/sitemap.xml</code> (or <code>/sitemap_index.xml</code> if WordPress/Yoast/Rank Math, which the <code>/tag/</code> , <code>/category/</code> URL patterns strongly suggest is the CMS)	A missing or stale sitemap slows discovery of new/updated pages.	Confirm the sitemap resolves, is submitted in Google Search Console, and its "last submitted"/"last read" dates are recent. Since the URL structure (<code>/tag/...</code> , <code>/category/...</code> , <code>/docs-category/...</code>) is classic WordPress + SEO plugin output, this is very likely already auto-generated — just confirm it's live and clean (no 404s, no <code>noindex</code> d URLs listed).
Legacy duplicate homepage indexed [Index-derived]	<code>https://www.retailzpos.com/home-old/</code> — indexed with title <i>"Retail POS System All-in-One Point of Sale Software Retailzpos"</i> , distinct from the live homepage title <i>"Best Retail POS System for Small Businesses RetailzPOS"</i>	A second full homepage-equivalent page is live and indexed. This splits link equity, risks duplicate-content flags, and confuses users who land on it from old backlinks/bookmarks.	301-redirect <code>/home-old/</code> to <code>/</code> . If it must stay live for internal reasons, add <code><meta name="robots" content="noindex,follow"></code> and a <code>rel=canonical</code> pointing to <code>/</code> . Request removal in GSC after the redirect is live.
Second live, separately-indexed	<code>https://retailzpos.com/ca/</code> (bare, non-www) is indexed with its own distinct title, <i>"RetailzPOS – Best Smoke &</i>	Two indexable domains/hostnames serving live	Decide the intended architecture: either (a) <code>retailzpos.com</code> (bare) should 301 to <code>www.retailzpos.com</code> sitewide and the Canada content should live at

Issue	Where	Why it matters	Recommended fix
domain [Index-derived]	<i>Retail POS System Canada</i> ", plus its own sub-pages: <code>retailzpos.com/ca/category/convenience-store-pos/</code> , <code>retailzpos.com/ca/tag/point-of-sale-pos-system/</code> . This is separate from <code>www.retailzpos.com</code> .	content (not one redirecting to the other) split domain authority and create duplicate/near-duplicate content risk between the US site on <code>www.</code> and Canada content on the bare apex. This is exactly the "duplicate content via <code>www</code> vs non- <code>www</code> " pattern flagged in the audit brief — confirmed live in the index.	<code>www.retailzpos.com/ca/</code> , or (b) if a genuinely separate Canada property is intentional, add explicit <code>hreflang="en-us" / hreflang="en-ca"</code> reciprocal tags between the two and unique canonical tags on each so Google doesn't treat them as duplicates. Right now neither signal is confirmed present.
Could not verify HTTPS-enforcement / redirect chain behavior	<code>http://retailzpos.com</code> , <code>http://www.retailzpos.com</code> , <code>https://retailzpos.com</code> → expected all to funnel to <code>https://www.retailzpos.com</code>	Redirect chains (>1 hop) waste crawl budget and slow first paint; a non-enforced HTTP version is a duplicate-content and security issue.	Team should verify with <code>curl -IL</code> from a machine with real network access: each of the three variants should return a single <code>https://www.</code> URL (except the <code>/ca/</code> case above, which needs its own decision first).
Could not verify <code>noindex</code> / <code>X-Robots-Tag</code> usage	Sitewide	An accidental <code>noindex</code> on a money page (or a page that should be de-indexed still being indexable) is a common, high-impact production bug.	Spot-check <code>/</code> , <code>/pricing/</code> , <code>/features/</code> , <code>/liquor-store-pos-system/</code> , <code>/smoke-shop-pos-system/</code> , <code>/blog/</code> in GSC's URL Inspection tool for indexing status and any <code>noindex</code> signal, plus check response headers for <code>X-Robots-Tag</code> .

B. On-Page / Meta Tags

Issue	Where	Why it matters	Recommended fix
Duplicate, non-descriptive <code><title></code> reused across	Confirmed via Google's indexed titles on at least these four URLs, all sharing the exact title <i>"Retail operations with our retail</i>	Duplicate titles are one of the most basic on-page SEO failures GSC's	Write unique, keyword-targeted titles per page, e.g.: <code>/pricing/</code> → <code>"RetailzPOS Pricing POS System Plans for Liquor,</code>

Issue	Where	Why it matters	Recommended fix
unrelated pages [Index-derived]	<i>pos system.</i> ": https://www.retailzpos.com/pricing/ , https://www.retailzpos.com/login/ , https://www.retailzpos.com/order-form/ , https://www.retailzpos.com/oh/liquor/	"Coverage"/"HTML Improvements" surfaces flag. /pricing/ is a high commercial-intent page and /oh/liquor/ is a localized landing page — both are being handed a generic, keyword-empty title instead of one that could actually rank.	Convenience & Smoke Shops"; /oh/liquor/ → "Liquor Store POS System in Ohio RetailzPOS"; /login/ and /order-form/ are utility pages and arguably should be <code>noindex</code> ed rather than given SEO titles at all (see Prioritized Actions, P1).
Could not verify meta description on any page	Sitewide	Meta description doesn't affect rankings directly but strongly affects SERP click-through rate.	Team should audit meta descriptions per template (homepage, vertical landing pages, blog posts, tag/category archives) — likely many are auto-generated/blank given the WordPress-pattern URL structure, which produces Google-generated snippets instead of controlled ones.
Could not verify canonical tags, Open Graph/ Twitter card tags, hreflang, or viewport meta	Sitewide	These require reading raw <code><head></code> HTML, which this session could not fetch. Canonical tags in particular are the direct fix for the www/ non-www duplication issue above.	Verify with "View Source" or Screaming Frog: confirm every page has a self-referencing (or correctly cross-referencing) <code>rel=canonical</code> , OG/Twitter tags exist for social sharing on money pages and blog posts, and <code><meta name="viewport" content="width=device-width, initial-scale=1"></code> is present sitewide.
Possible geographic/ NAP inconsistency [Index-derived]	The indexed title for / features/ reads "POS Features RetailzPOS Atlanta Georgia", while the company's contact/social listings (Facebook, review sites) list the address as Griffin, GA .	Griffin is in the greater Atlanta metro, so this isn't necessarily wrong, but inconsistent city naming across title tags, Google Business Profile, and citations can weaken local SEO / NAP consistency signals if not deliberate.	Confirm whether "Atlanta" is an intentional metro-area branding choice; if so, use it consistently (and consider whether Griffin should also appear for local-pack relevance). If not intentional, standardize on the actual registered business city across title tags, schema, and citations.

C. Structured Data

Issue	Where	Why it matters	Recommended fix
Could not verify any JSON-LD / schema.org markup	Sitewide	Could not fetch raw HTML, so presence/absence of <code>Organization</code> , <code>SoftwareApplication</code> / <code>Product</code> , <code>LocalBusiness</code> , <code>FAQPage</code> , <code>BreadcrumbList</code> , or <code>Review</code> / <code>AggregateRating</code> schema is unconfirmed.	Run pages through Google's Rich Results Test / Schema.org validator directly. Given strong third-party ratings already exist (Birdeye 4.5★/30 reviews, Capterra, GetApp, Software Advice, Trustpilot 3.8★), if <code>AggregateRating</code> schema isn't already implemented on the homepage/product pages, it's a concrete opportunity for star-rating rich snippets in search — but only implement it if the ratings shown match what's genuinely aggregated and current per Google's review-snippet policy (don't self-declare a rating not backed by an on-page review count).
Recommend <code>BreadcrumbList</code> schema given deep URL structure	Pages like <code>/category/liquor-pos-system/</code> , <code>/oh/liquor/</code> , <code>/docs-category/dashboard/</code>	The URL structure suggests multi-level taxonomy (state/vertical, category, tag). Breadcrumb rich results improve SERP real estate and help Google understand site hierarchy.	Add <code>BreadcrumbList</code> JSON-LD matching the visible breadcrumb trail (Home > Liquor POS > Ohio, etc.) if not already present — unverified either way.

D. Site Architecture & Internal Linking

Issue	Where	Why it matters	Recommended fix
Keyword cannibalization on "liquor store POS system" [Index-derived]	At least three/four indexed URLs compete for essentially the same head term: <code>/liquor-store-pos-system/</code> (flagship landing page), <code>/liquor-store-pos-systems-2026/</code> (blog "buyer's guide" post), <code>/category/liquor-pos-system/</code> (category archive), plus multiple near-identical <code>/tag/</code> pages (<code>/tag/liquor-store/</code> , <code>/tag/liquor-pos/</code> , <code>/tag/best-</code>	When several URLs on the same domain target the same query, Google has to choose which to rank and often suppresses the others or alternates — diluting authority instead of consolidating it into one strong page.	Designate <code>/liquor-store-pos-system/</code> as the single canonical "money page" for that term. Internally link the blog post and category/tag pages to it with descriptive anchor text. Consider <code>noindex</code> ing the thinnest <code>/tag/</code> variants (see next row) rather than letting them compete.

Issue	Where	Why it matters	Recommended fix
	liquor-store-pos-system/ , /tag/best-pos-system-for-liquor-store/)		
WordPress tag-archive index bloat [Index-derived]	Confirmed indexed: /tag/liquor-store/ , /tag/liquor-pos/ , /tag/best-liquor-store-pos-system/ , /tag/best-pos-system-for-liquor-store/ , /tag/convenience-store-pos-software/ , /tag/convenience-store-pos-system/ , /tag/smoke-shop-business/ , /tag/smoke-shop-pos-providers/ , /tag/best-smoke-shop-pos/ , /tag/customer-loyalty-programs/ , and more	WordPress tag archives are typically thin (just a list of post excerpts) and frequently near-duplicates of each other and of the category pages. At the volume implied here, this is classic index bloat that dilutes crawl budget and topical authority.	Either <code>noindex</code> , follow the <code>/tag/</code> archive template sitewide (keep it for internal UX/navigation, remove it from Google's index) or prune to a small set of genuinely useful tags. Keep the <code>/category/</code> pages if they're more substantive, but audit them for the same thinness.
No confirmed flagship US "Convenience Store POS" landing page [Index-derived, low confidence]	Search turned up a Canada-path convenience-store category page (<code>retailzpos.com/ca/category/convenience-store-pos/</code>) and several <code>/tag/</code> pages, plus a blog post ("How To Start A Convenience Store Business"), but no equivalent US www page to <code>/liquor-store-pos-system/</code> or <code>/smoke-shop-pos-system/</code> was found in the index for convenience stores.	If accurate, this is a gap: convenience stores are one of RetailzPOS's three named core verticals but may lack a dedicated, optimized <code>www.retailzpos.com/convenience-store-pos-system/</code> landing page equivalent to the other two verticals.	Flagged as needs confirmation — I could not browse the live site nav/sitemap to confirm this page truly doesn't exist. Team should check directly; if it's missing, build it using the same template as <code>/liquor-store-pos-system/</code> and <code>/smoke-shop-pos-system/</code> , targeting "convenience store POS system" / "c-store point of sale software."
Could not verify internal link structure or broken links	Sitewide	Requires crawling the rendered site, which this session could not do.	Run a Screaming Frog crawl (or similar) for orphan pages, broken internal links, and redirect chains — none of which could be checked here.

E. Performance Signals

Issue	Where	Why it matters	Recommended fix
Could not measure response time, payload size, or Core Web Vitals	Homepage and key pages	This session had no working outbound HTTP access (see Methodology note), so <code>curl -w</code> timing data, TTFB, page weight, and any Lighthouse/CWV figures are unavailable — I have not fabricated any LCP/INP/CLS numbers.	Run <code>https://pagespeed.web.dev/</code> (Lighthouse) and check the CWV report in Google Search Console (field data, not lab data) for the actual LCP/INP/CLS distribution across real users. This is the single most important unfilled gap in this audit and should be run before prioritizing performance work.

F. Mobile / Technical

Issue	Where	Why it matters	Recommended fix
Could not verify viewport meta tag or responsive rendering	Sitewide	Could not fetch raw HTML or render the page.	Run Google's Mobile-Friendly Test (or just inspect on a phone) to confirm responsive layout and a proper viewport meta tag.
Could not verify mixed content (HTTP resources on HTTPS pages)	Sitewide	Mixed content triggers browser warnings and can block resources, hurting UX and Core Web Vitals.	Check DevTools console for mixed-content warnings on key pages.

G. Content Gaps for the Liquor / Convenience / Smoke Shop ICP

This is the one area where the finding runs **counter to the audit brief's working assumption** — worth stating plainly: **RetailzPOS does not have a content-gap problem for these verticals; it has a content-consolidation problem.** [Index-derived]

Confirmed live, indexed vertical content includes: - **Liquor:** `/liquor-store-pos-system/`, `/liquor-store-pos-systems-2026/` (buyer's guide), `/category/liquor-pos-system/`, `/oh/liquor/` (state-localized page), plus multiple supporting tag pages and messaging around age verification, case-break inventory cascading, and mix-and-match pricing. - **Smoke shop / vape:** `/smoke-shop-pos-system/`, blog content on cloud-based POS for smoke shops, messaging around tobacco scan-data compliance and managing vape SKU variations by flavor/nicotine strength. - **Convenience store:** `/tag/convenience-store-pos-software/`, `/tag/convenience-store-pos-system/`, a "How To Start A Convenience Store Business" blog post, and a Canada-path category page — but (per section D above) possibly missing a flagship US landing page equivalent to the other two verticals.

Real opportunities here are structural, not "does content exist": 1. **Consolidate, don't multiply** — stop the liquor-vertical cannibalization (section D) before adding more liquor content. 2. **Close the convenience-store flagship-page gap** if confirmed missing (section D). 3. **Expand state/local pages deliberately, not thinly** — `/oh/liquor/` shows the pattern (vertical × state) already exists for at least Ohio. If this is meant to scale to more states (a strong local-SEO play for "liquor store POS system near me"-style queries), each page needs genuinely unique local content (licensing/compliance notes relevant to that state's ABC laws, local case studies)

— not templated boilerplate, or it becomes more index bloat like the `/tag/` problem above. I could not confirm how many states currently have pages or how differentiated their content is. 4. **CBD** was mentioned in search snippets as an adjacent vertical RetailzPOS already serves — if there's no dedicated CBD-store landing page, that's a genuine smaller gap worth a quick check, since it's adjacent to both liquor and smoke shop compliance needs.

3. Prioritized Action List

P0 — Critical / do first 1. Get direct network access to the live site (Screaming Frog, GSC, PageSpeed Insights, or plain `curl`) and run the raw technical checks this audit could not perform: headers, robots.txt, sitemap.xml, canonical tags, `noindex` status on money pages, and redirect-chain behavior for `http://`, `non-www`, and `www` variants. 2. Resolve the **www vs. non-www / retailzpos.com vs retailzpos.com/ca/** domain split — decide the intended architecture and implement 301s and/or hreflang + canonical tags accordingly. 3. Fix the **duplicate title tag** ("Retail operations with our retail pos system.") on `/pricing/`, `/login/`, `/order-form/`, `/oh/liquor/` at minimum — audit the full site for the same template default. 4. Redirect or `noindex` `/home-old/`.

P1 — High 5. Consolidate the **liquor-vertical cannibalization**: pick `/liquor-store-pos-system/` as the canonical page, internally link supporting content to it, `noindex` the thinnest overlapping `/tag/` pages. 6. `noindex` (or prune) the broader **WordPress /tag/ archive bloat** across all verticals. 7. Confirm/build a **flagship US convenience-store landing page** if genuinely missing. 8. Run **PageSpeed Insights / GSC Core Web Vitals report** — currently a complete unknown.

P2 — Medium 9. Verify/implement **structured data** (Organization, SoftwareApplication, AggregateRating sourced from real review counts, BreadcrumbList). 10. Resolve the **Atlanta vs. Griffin, GA** naming inconsistency across title tags, schema, and citations. 11. Reconsider the **/pricing/ page strategy** — currently appears to route to a contact/demo form rather than publish real pricing; third-party sites (Capterra, GetApp) are capturing "RetailzPOS pricing" search intent that could otherwise land on-domain.

P3 — Nice to have 12. Add/verify **AI-crawler access** (GPTBot, ClaudeBot, PerplexityBot, Google-Extended) in robots.txt and consider an `llms.txt` for AI Overview / answer-engine visibility. 13. If scaling state-level landing pages (the `/oh/liquor/` pattern), ensure each has genuinely unique local content before expanding — don't scale the template before fixing the cannibalization/bloat issues above. 14. Evaluate a dedicated **CBD store** landing page given the vertical is already referenced in existing content.

4. Explicitly Not Verified (do not treat as "passed")

Because this session's outbound network access was blocked at the environment/proxy level for **all** external hosts (confirmed via control tests, not specific to retailzpos.com), the following were **not checked** and should not be assumed fine just because they aren't listed as problems above:

- Actual HTTP status codes and response headers for any page
- `robots.txt` file contents

- `sitemap.xml` / sitemap index contents and validity
- HTTPS enforcement and exact redirect chain (hop count) for `http` → `https` and `non-www` → `www`
- `rel=canonical` tags on any page
- `hreflang` tags
- Open Graph / Twitter Card tags
- JSON-LD / `schema.org` structured data presence, type, or validity
- Exact meta description text/length on any page
- H1/H2 heading structure, including whether any page has zero or multiple H1s
- Image `alt` attribute coverage
- Full internal link graph / orphan pages / broken links
- True Core Web Vitals (LCP, INP, CLS) — lab or field data
- Actual page weight / TTFB / response time
- Mobile rendering and viewport meta tag
- Mixed-content issues
- Full on-page copy quality and keyword density on any page (index-derived summaries above are Google's own AI-generated characterizations of search results, not this auditor's direct reading of the page copy)

Recommendation: re-run this audit (or at minimum the "Could Not Verify" list) with a tool or environment that has genuine outbound access to `retailzpos.com` — e.g., Screaming Frog SEO Spider, Google Search Console, and PageSpeed Insights — before treating this report as complete. The findings above are real and actionable, but they are index-derived, not header/HTML-derived, and should be spot-checked directly.
